Tutorial #3

Security in Computing COSC2356/2357

Q1. Basic mathematics

- **a.** Which of the following numbers is not a prime number 313,317,379,887,983, 992, 997
- **b.** What is the GCD of 8 and 12? GCD(8,12)=?
- **c.** What is the GCD of 9 and 21? GCD(9,21)=?
- **d.** What is the GCD of 9 and 11? GCD(9,11)=?
- **e.** What are values of 51 mod 5=? and 389 mod 77=?
- **f.** Find two coprime numbers. In other words, if GCD (a,b)=1 find out a suitable pair of a and b.
- **g.** Are 6 and 30 coprime?
- **h.** Find out LCM(30,60) and LCM(14, 21)

Ans:

a) 992

b) 4

c) 3

d) 1

e) 51 mod 5 = 1, and 389 mod 77 = 4

f) For example, 9 and 11 are coprimes to each other as GCD(9,11) = 1

g) No, 6 and 30 are not coprime, as GCD(6,30) = 6, which is not equal to 1.

h) LCM(30,60) = 60, and LCM(14, 21) = 42

Q2. Modular mathematics

Using the following online calculator, find the value of the expressions:

Power MOD Calculator: https://www.mtholyoke.edu/courses/quenell/s2003/ma139/js/powermod.html

Inverse MOD Calculator:

https://planetcalc.com/3311/

- i. 10^{19} mod 33
- ii. 5^{11} mod 77
- iii. 7^{-1} mod 33
- iv. 23^{-1} mod 551

Ans:

To find the value of the expressions given in (i) and (ii), we use the following online **power mod calculator**:

https://www.mtholyoke.edu/courses/quenell/s2003/ma139/js/powermod.html

i. 10^{19} mod 33 = 10

Base: 10	Exponent: 19	Modulus: 33
Compute	b^e MOD m =	10

ii. 5^{11} mod 77 = 38

Base: 5	Exponent: 11	Modulus: 77
Compute	b^e MOD m =	38

To find the value of the expressions given in (iii) and (iv), we use the following online **inverse mod calculator**: https://planetcalc.com/3311/

iii. 7^{-1} mod 33 = 19

Q2 (Simple RSA Encryption -I)

Bob is a receiver and Alice is a sender. Bob generates public and private keys using RSA encryption algorithm and sends the public key to Alice. Alice has a message ***M*=100** to send. Bob uses parameter ***p*=19** and ***q*=29**, and chooses a small public key parameter ***e*.** What are the values of suitable public and private keys**?** How would Alice encrypt message ***M*=100**? How would Bob decrypt the encrypted message ***C*** with the private key? (**Note**: do it with online calculator or computer program)

- Say, the message is $M = 100$
- Pick two prime numbers $p = 19$ and $q = 29$
- Calculate $n = p * q = 19 * 29 = 551$
- Calculate $\phi(n) = (p-1) * (q-1) = (19-1) * (29-1) = 504$
- Choose a prime number e, such that e is co-prime to $\phi(n)$, i.e, $\phi(n)$ is not divisible by e. Let e be $1 < e < \phi(n)$. In other words, $gcd(e, 504) = 1$ We have several choices for e. Let's pick e=59
- Server generates private key to decrypt the encrypted message sent by the browser. Let d be the private key. Then $de = 1\ mod\ \phi(n)$. Here, $d * 59 = 1\ mod\ 504$. Using Extended Euclid Algorithm $d = 299$
- Encryption using public key:
  $C = M^e\ mod\ n = 100^{59}\ mod\ 551 = 370$
- Decryption using Private key
  $M = C^d\ mod\ n = 370^{299}\ mod\ 551 = 100$

<u>Q3 (Simple RSA Encryption -II)</u>

Bob is a receiver and Alice is a sender. Bob generates public and private keys using RSA encryption algorithm and sends the public key to Alice. Alice has a message ***M*=2** to send. Bob uses parameter ***p*=3** and ***q*=11**, and chooses a small public key parameter ***e*.** What are the values of suitable public and private keys**?** How would Alice encrypt message ***M*=2**? How would Bob decrypt the encrypted message ***C*** with the private key? (**Note**: do it manually without online calculator or computer program)

- Say, the message is $M = 2$
- Pick two prime numbers $p = 3$ and $q = 11$
- Calculate $n = p * q = 3 * 11 = 33$
- Calculate $\phi(n) = (p-1) * (q-1) = (3-1) * (11-1) = 20$
- Choose a prime number e, such that e is co-prime to $\phi(n)$, i.e, $\phi(n)$ is not divisible by e. Let e be $1 < e < \phi(n)$. In other words, $gcd(e, 20) = 1$ We have several choices for e. Let's pick e=7
- Server generates private key to decrypt the encrypted message sent by the browser. Let d be the private key. Then $de = 1 \ mod \ \phi(n)$. Here, $d * 7 = 1 \ mod \ 20$. Using Extended Euclid Algorithm $d = 3$
- Encryption using public key:
  $C = M^e \ mod \ n = 2^7 \ mod \ 33 = 29$
- Decryption using Private key
  $M = C^d \ mod \ n = 29^3 \ mod \ 33 = 2$

Q4 (Breaking RSA)

Bob is a receiver and Alice is a sender. Bob generates public and private keys using RSA encryption algorithm and publishes the public key (***n=481, e=47***). Alice has a secret message ***M*** to send. Nobody knows the value of ***M.*** She encrypts the message ***M*** using the public key and sends the encrypted message ***C=463*** to Bob. Trudy is an intruder and knows RSA and prime factorization well. She captures the encrypted message ***C=463***. She also has the public key (***n=481, e=47***) because it is known to all. How can he decrypt the encrypted message ***C*** and find the value ***of M***?

- Say, Let's factor $n = 481$
- The prime numbers are: $p = 13$ and $q = 37$ (because $n = p * q = 13 * 37 = 481$)
- Calculate $\phi(n) = (p-1) * (q-1) = (13-1) * (37-1) = 432$
- Here, e=47
- Let d be the private key. Then $= 1\, mod\, \phi(n)$. Here, $d * 47 = 1\, mod\, 432$. Using Extended Euclid Algorithm d
- Also, given is $C = 463$
- Decryption using Private key
  $M = C^d\, mod\, n = 463^{239}\, mod\, 481 = 200$
- We can also verify that encryption using public key generates intended value:
  $C = M^e\, mod\, n = 200^{47}\, mod\, 481 = 463$

Task 1 (Demonstration of RSA Cryptosystems using Java and Python programming Language)

Log in to your CANVAS and download the code of a very simple RSA encryption scheme. There are two files in the CANVAS: **RSAEncryption.java** and **RSAEncryption.py**. Download and run either of the file based on your familiarity on **JAVA** and **Python** programming language. Use **Q2** and **Q3** for required information.
The codes are given as follows:

********************** JAVA CODE :: File Name: RSAEncryption.java********************

de $= 239$

```
import java.math.BigInteger;
import java.util.Scanner;

public class RSAEncryption {

	public static void main(String[] args) {
		  // Declare required parameters as BigInteger objects
		BigInteger m;       //     Input Message
		BigInteger p;       //     1st prime number
		BigInteger q;       //     2nd prime number
		BigInteger n;       //     Key parameter "n"
		BigInteger phi_n;   //     Function Phi(n)
		BigInteger e;       //     Public Key parameter "e"
		BigInteger d;       //     Private Key parameter "d"
		BigInteger C;       //     Encrypted Message
		BigInteger M;       //     Decrypted Message

		// Take required parameter as Input

		Scanner input = new Scanner(System.in); // initialize Scanner object for
taking input
```

```java
            System.out.println("Welcome to RSA Encryption Program !!!");
            System.out.println("Please provide the following information as Integer
!!!");
            System.out.print("Enter the message (as Integer) to encrypt, m := ");
            String m_str = input.next();

            System.out.print("Enter the value of 'P' (as Integer): ");
            String p_str = input.next();

            System.out.print("Enter the value of 'Q' (as Integer): ");
            String q_str = input.next();

            System.out.print("Enter the value of 'e' (as Integer): ");
            String e_str = input.next();

            // assign values to bi1, bi2
            m = new BigInteger(m_str);
            p = new BigInteger(p_str);
            q = new BigInteger(q_str);

            System.out.println();

            System.out.println("Here is the detail Solution: ");

            n = p.multiply(q);
            System.out.println("The value of 'n' is: "+n);

            phi_n = p.subtract(new BigInteger("1")).multiply(q.subtract(new
BigInteger("1")));
            System.out.println("The value of 'Phi(n)' is: "+phi_n);

            e = new BigInteger(e_str);

            System.out.println("The Public-Key (n,e) := ("+n+", "+e+")");

            d = e.modInverse(phi_n);
            System.out.println("The value of private key parameter 'd' is: "+d);
            System.out.println("The Private-Key (n,d) := ("+n+", "+d+")");

            C = m.modPow(e, n);

            System.out.println("Ciphertext, C := "+C);

            M = C.modPow(d, n);

            System.out.println("Extracted Message, M := "+M);
      }
}
```

******************** PYTHON CODE :: File Name: RSAEncryption.py*****************

```
# Function Declarations

def egcd(a, b): # Calculates Euclidian GCD,  return (g, x, y) ...  a*x + b*y =
gcd(x, y)

Plaintext 'M' is: "+ str (M))
```

Task 2 (RSA Publik-Key Encryption and Decryption using OpenSSL).

Windows OS:

Please download and install OpenSSl from the following link:

http://downloads.sourceforge.net/gnuwin32/openssl-0.9.8h-1-bin.zip

Unzip the file and run "**openssl.exe**".

Linux or recent MacOS:

You already have OpenSSL. Open terminal and run the following command:

```
>openssl
```

You are ready to run OpenSSL commands.

Using RSA Algorithm using OpenSSL

Assume that you have a plain-text file, called "**`plain-text.txt`**", with your *name* and *student ID* in that file. Apply Openssl's ***RSA algorithm*** for a **2048-bit key** to encrypt the "**`plain-text.txt`**" file. Say, the name of the cipher-text file is "**`cipher-text.txt`**". Now, decrypt the "**`cipher-text.txt`**" file using OpenSSL's **RSA algorithm**.

Answer:

Step-1: Generate 2048-bit RSA private/public key pairs using the following command. The private key is stored in key.pem.

```
genrsa -out key.pem 2048
```

You should get the following outputs in the console:
Generating RSA private key, 2048 bit long modulus
..................+++
....................................+++
e is 65537 (0x010001)

A file called **key.pem** is generated, which is the **Private-key**.

Step-2: See the detail key information using the following command:

```
rsa -in key.pem -text -noout
```

You should get the following output:

Private-Key: (2048 bit)
modulus:
```

Step-3: Extract RSA Public key from the private key using the following command:

```
rsa -in key.pem -pubout -out pub-key.pem -text
```

A file called **pub-key.pem** is generated, which is the public-key.

Step-4: Encrypt the plain-text file "**plain-text.txt**" with the public key **pub-key.pem** using the following command:

```
rsautl -in plain-text.txt -out cipher-text.txt -pubin -inkey pub- key.pem –
encrypt
```

An encrypted file called **cipher-text.txt** is generated, which contains something similar to the followings:

蘥 嗤轢┼뷃퇶쉬벱都 捙흚汘锶ꝓꝓ╟霗렱煥駏 秵簿嫣 誉讕轴樅瘙 瓊킨蹌憪

Step-5: At receiver's side, the encrypted file is decrypted with private key using the following command:

```
rsautl -in cipher-text.txt -out cipher-text-dec.txt -inkey key.pem  -decrypt
```

A file called `cipher-text-dec.txt` is generated, which is the decrypted file.
